

# Equivalent widths

- General methods
- Some examples

Equivalent widths are useful because can be easily converted into abundances, having a model atmosphere and the line parameters

Equivalent widths are independent of  $V_{\text{sini}}$  and  $V_{\text{mac}}$  broadening (you do not need to know  $V_{\text{sini}}$  and  $V_{\text{mac}}$  to measure abundances)

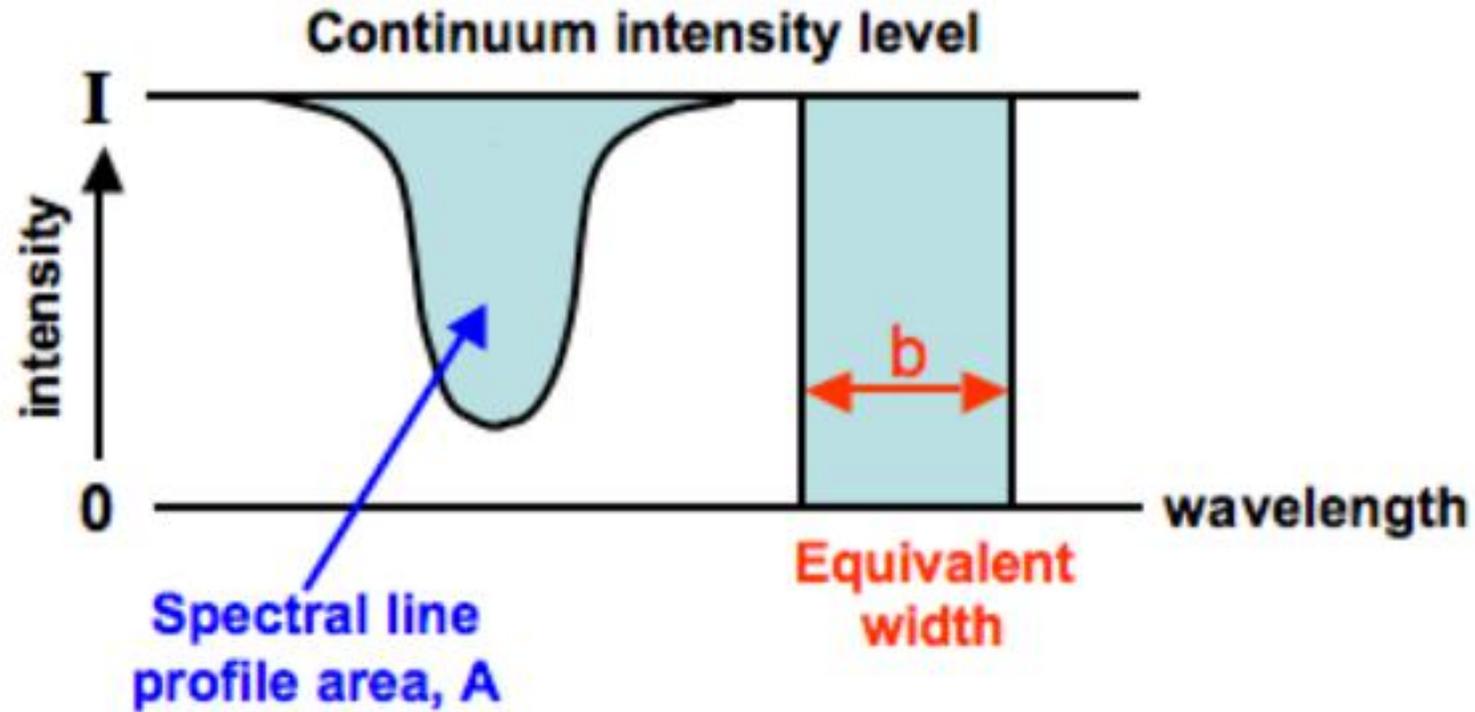

# Equivalent widths

- General methods
  - **Direct integration**
  - **Line profile fitting**
- Some examples

Equivalent widths are independent of  $V_{\text{sini}}$  and  $V_{\text{mac}}$  broadening (you do not need to know  $V_{\text{sini}}$  and  $V_{\text{mac}}$  to measure abundances)

# Equivalent widths: definition and direct integration

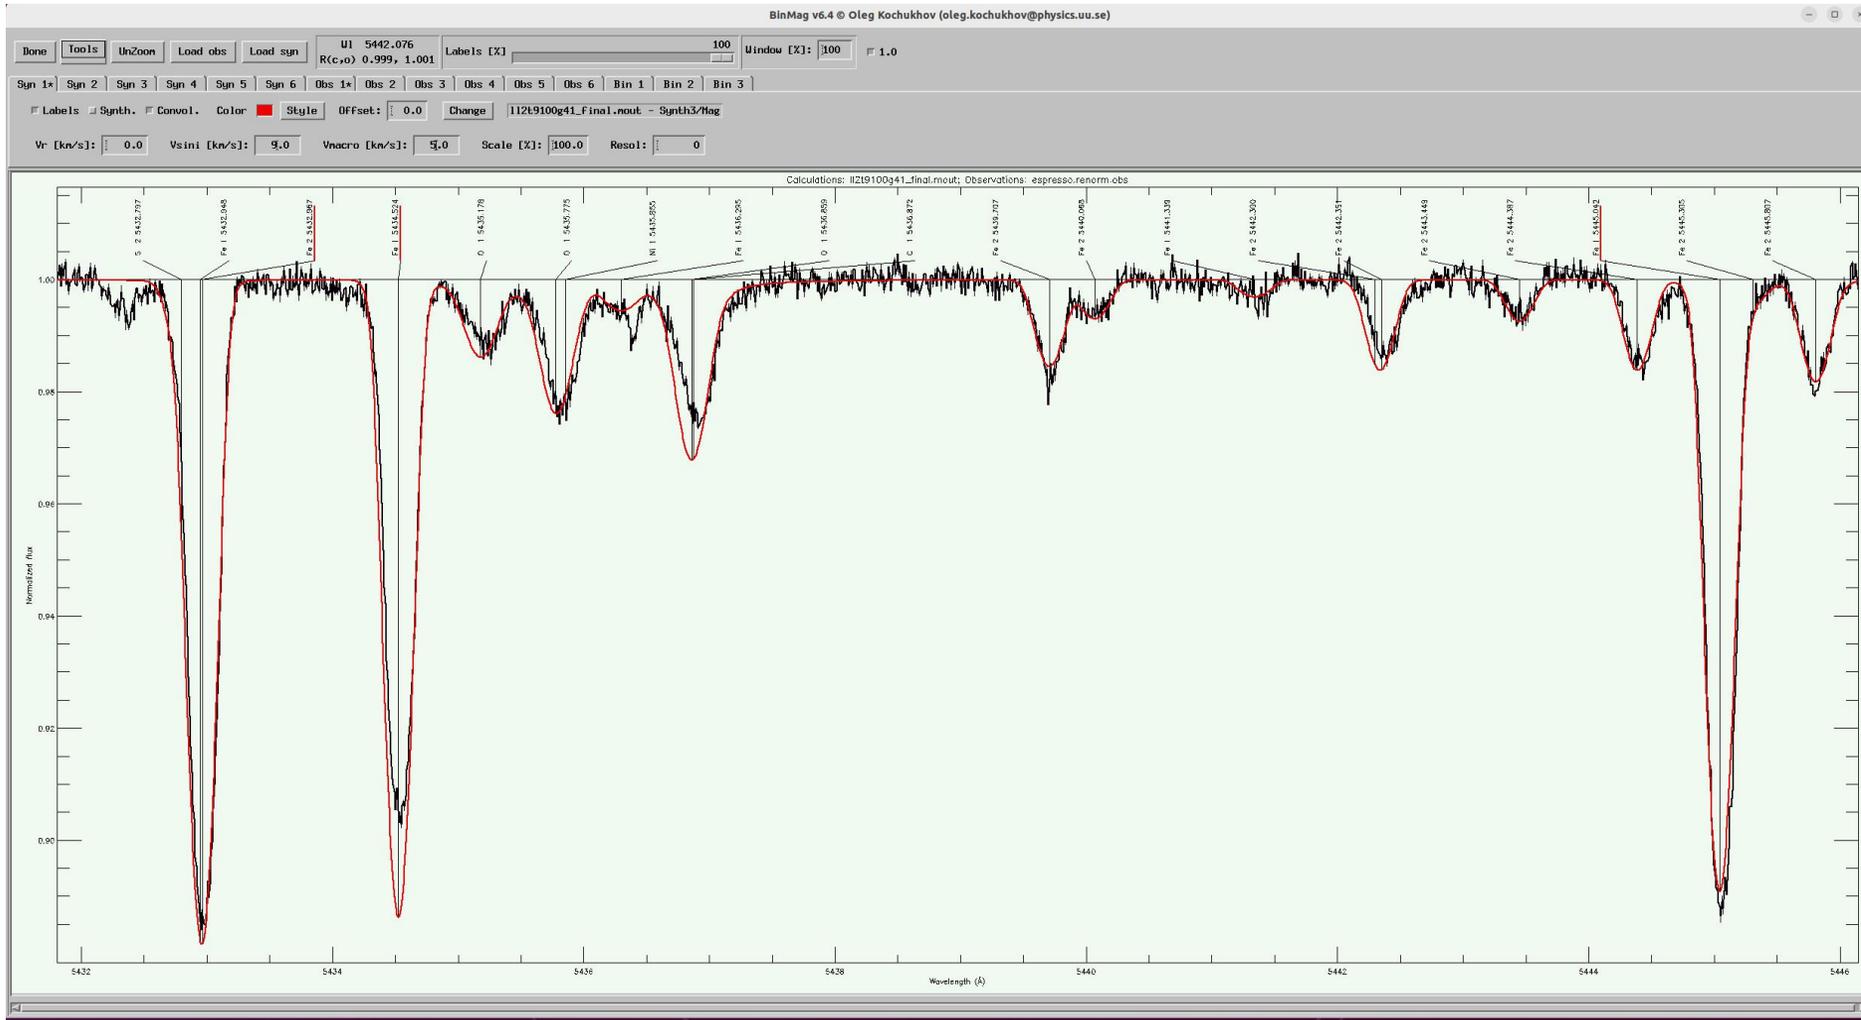

Equivalent widths are measured in milliAngstroms

One directly measures the area between a spectral line and the continuum

# Equivalent widths: line profile fitting

Spectral lines are typically Voigt profiles (convolution between Gaussian and Lorentzian profiles), however in most cases they can be approximated by either a gaussian or a rotational profile or a mix of the two

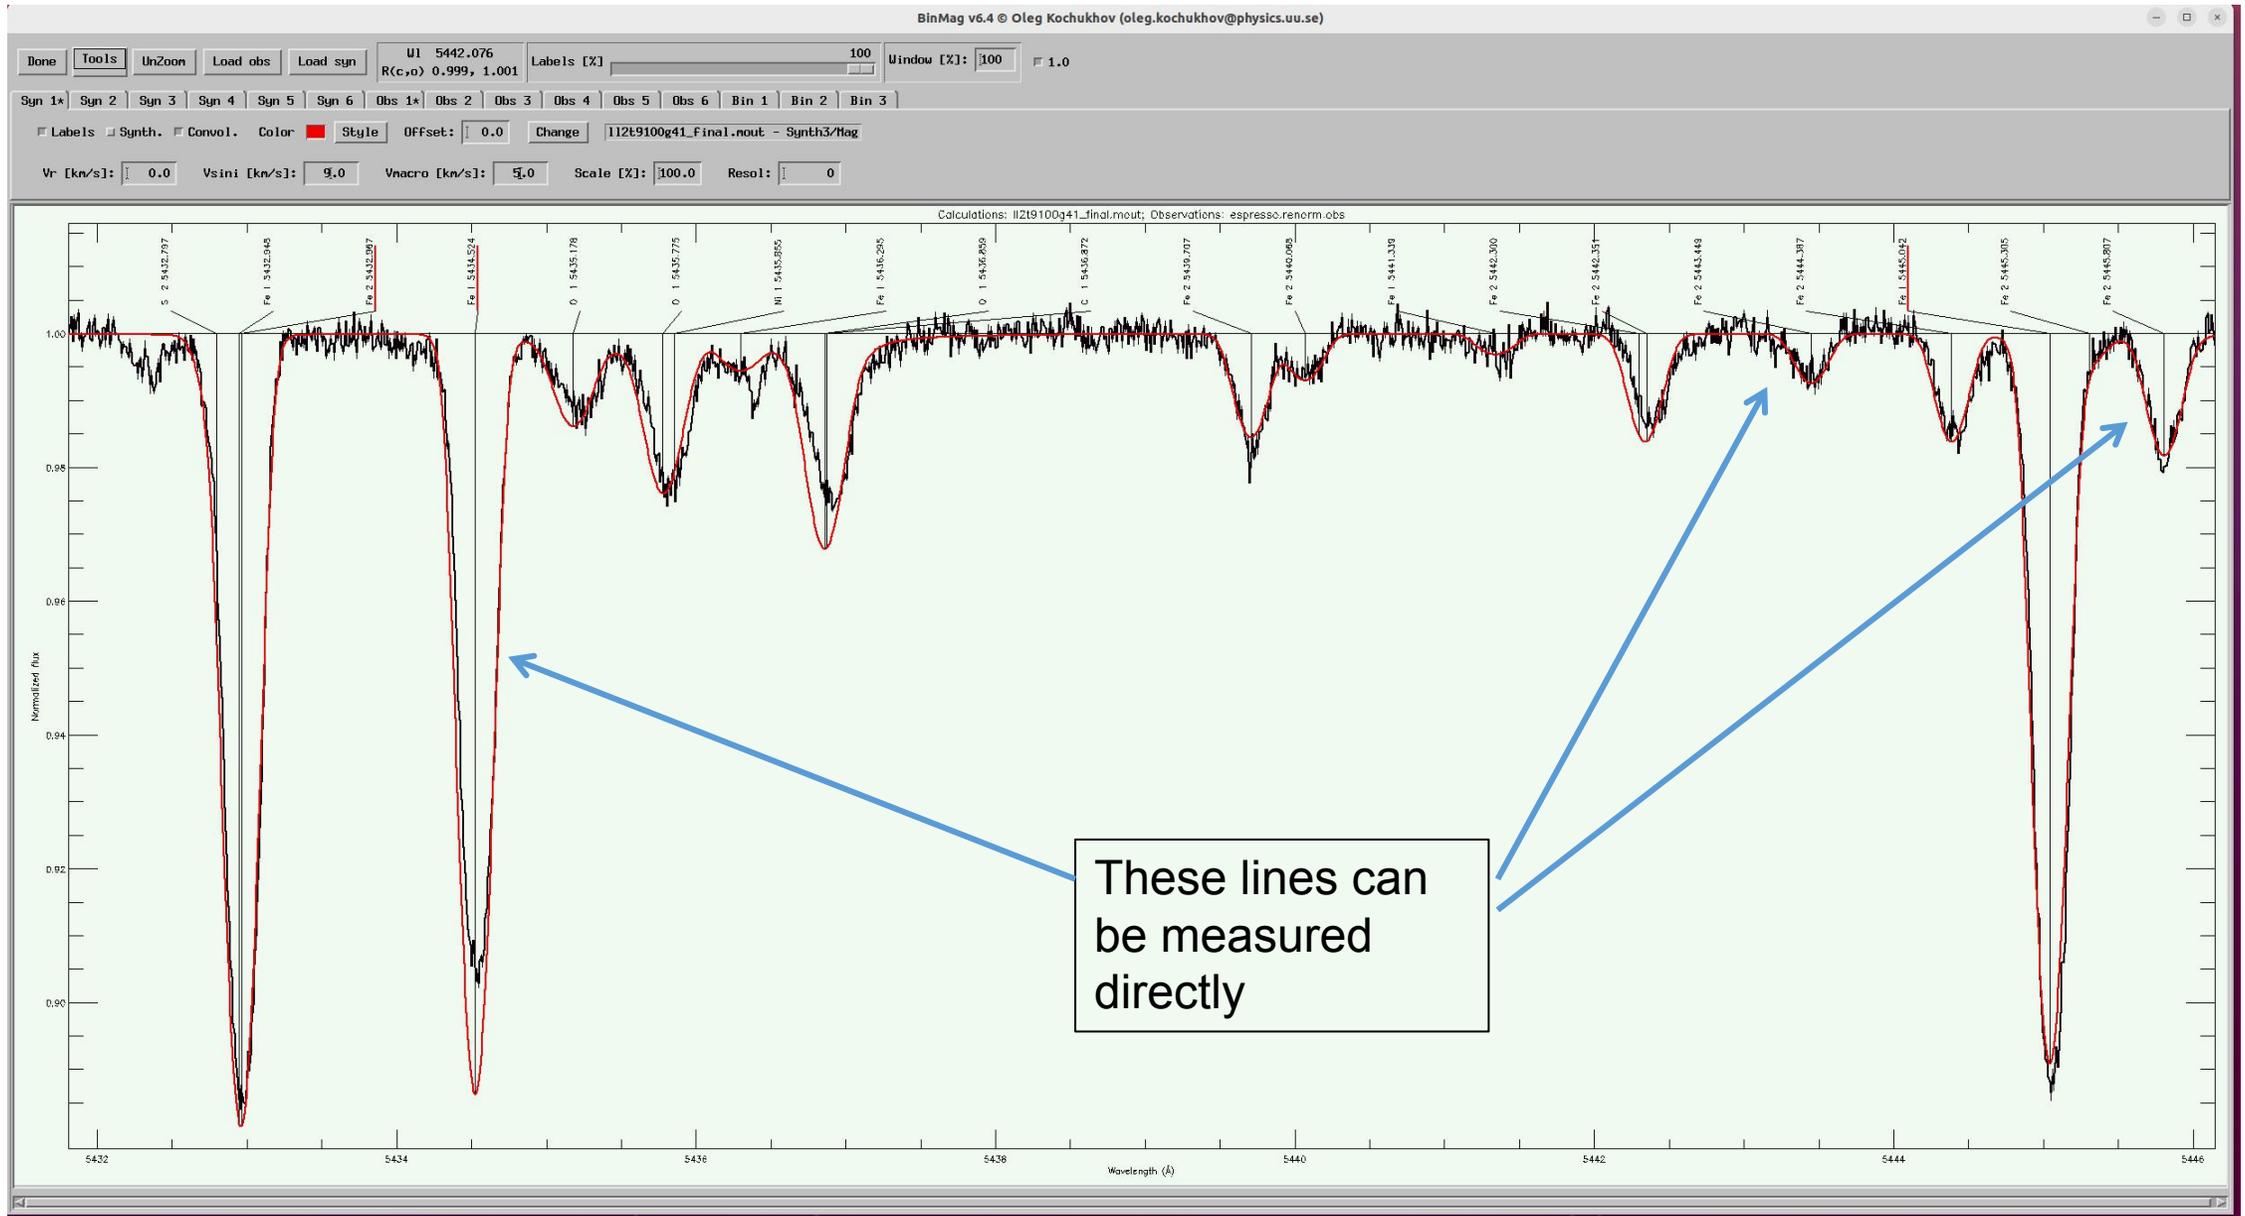

Binmag (IDL) by Oleg

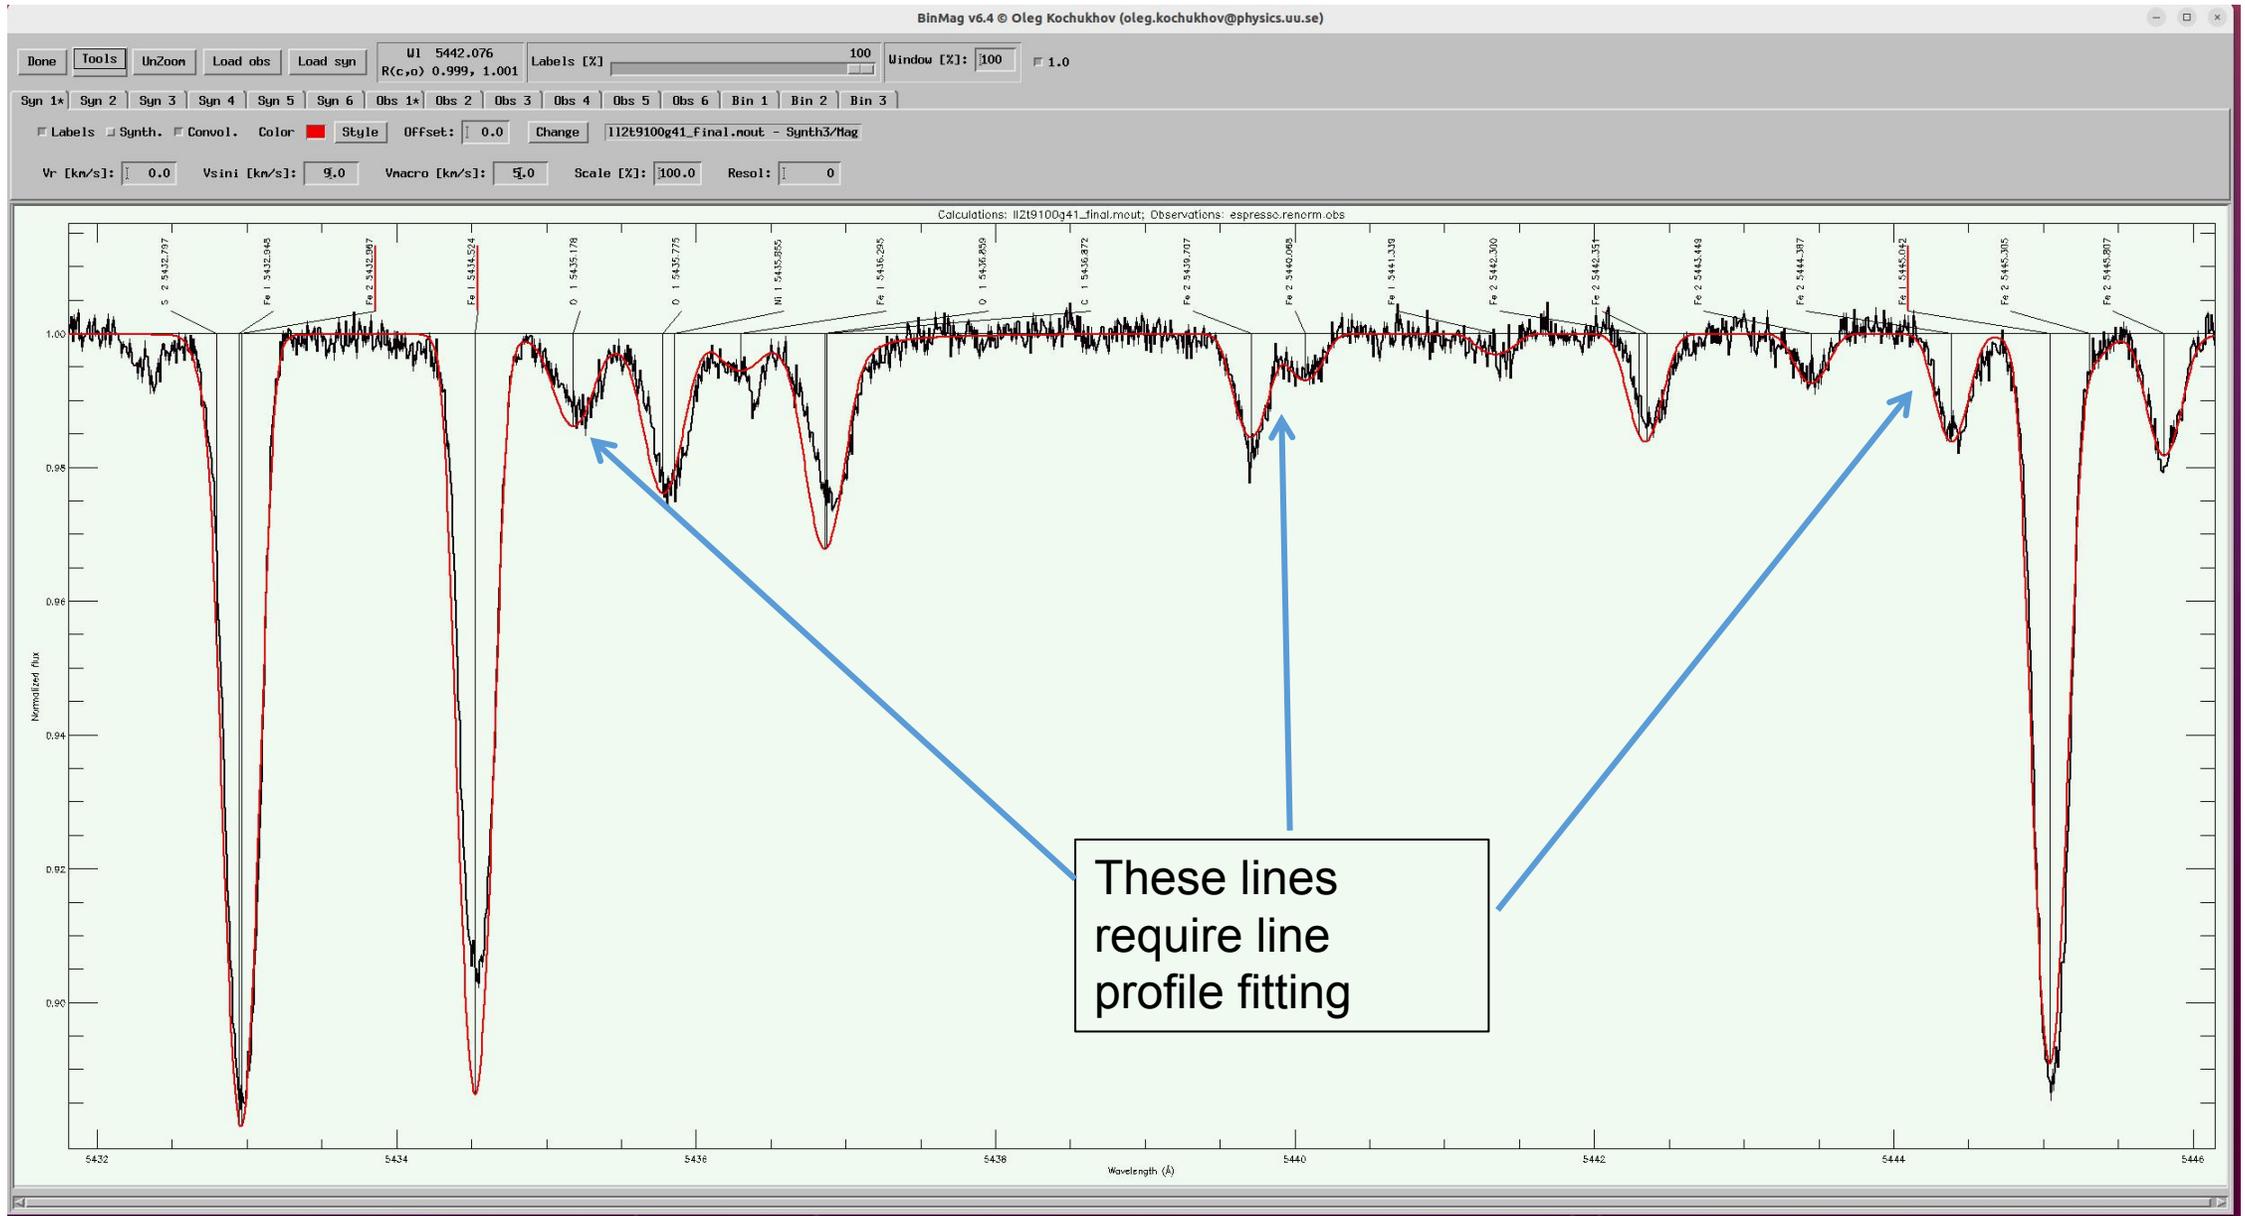

<https://www.astro.uu.se/~oleg/binmag.html>

Visualisation, fitting of various parameters (e.g.  $V_r$ ,  $V_{sini}$ ,  $V_{mac}$ ), measure equivalent widths using different methods, excellent for handling SB2, interface to SME for parameter and abundance determination

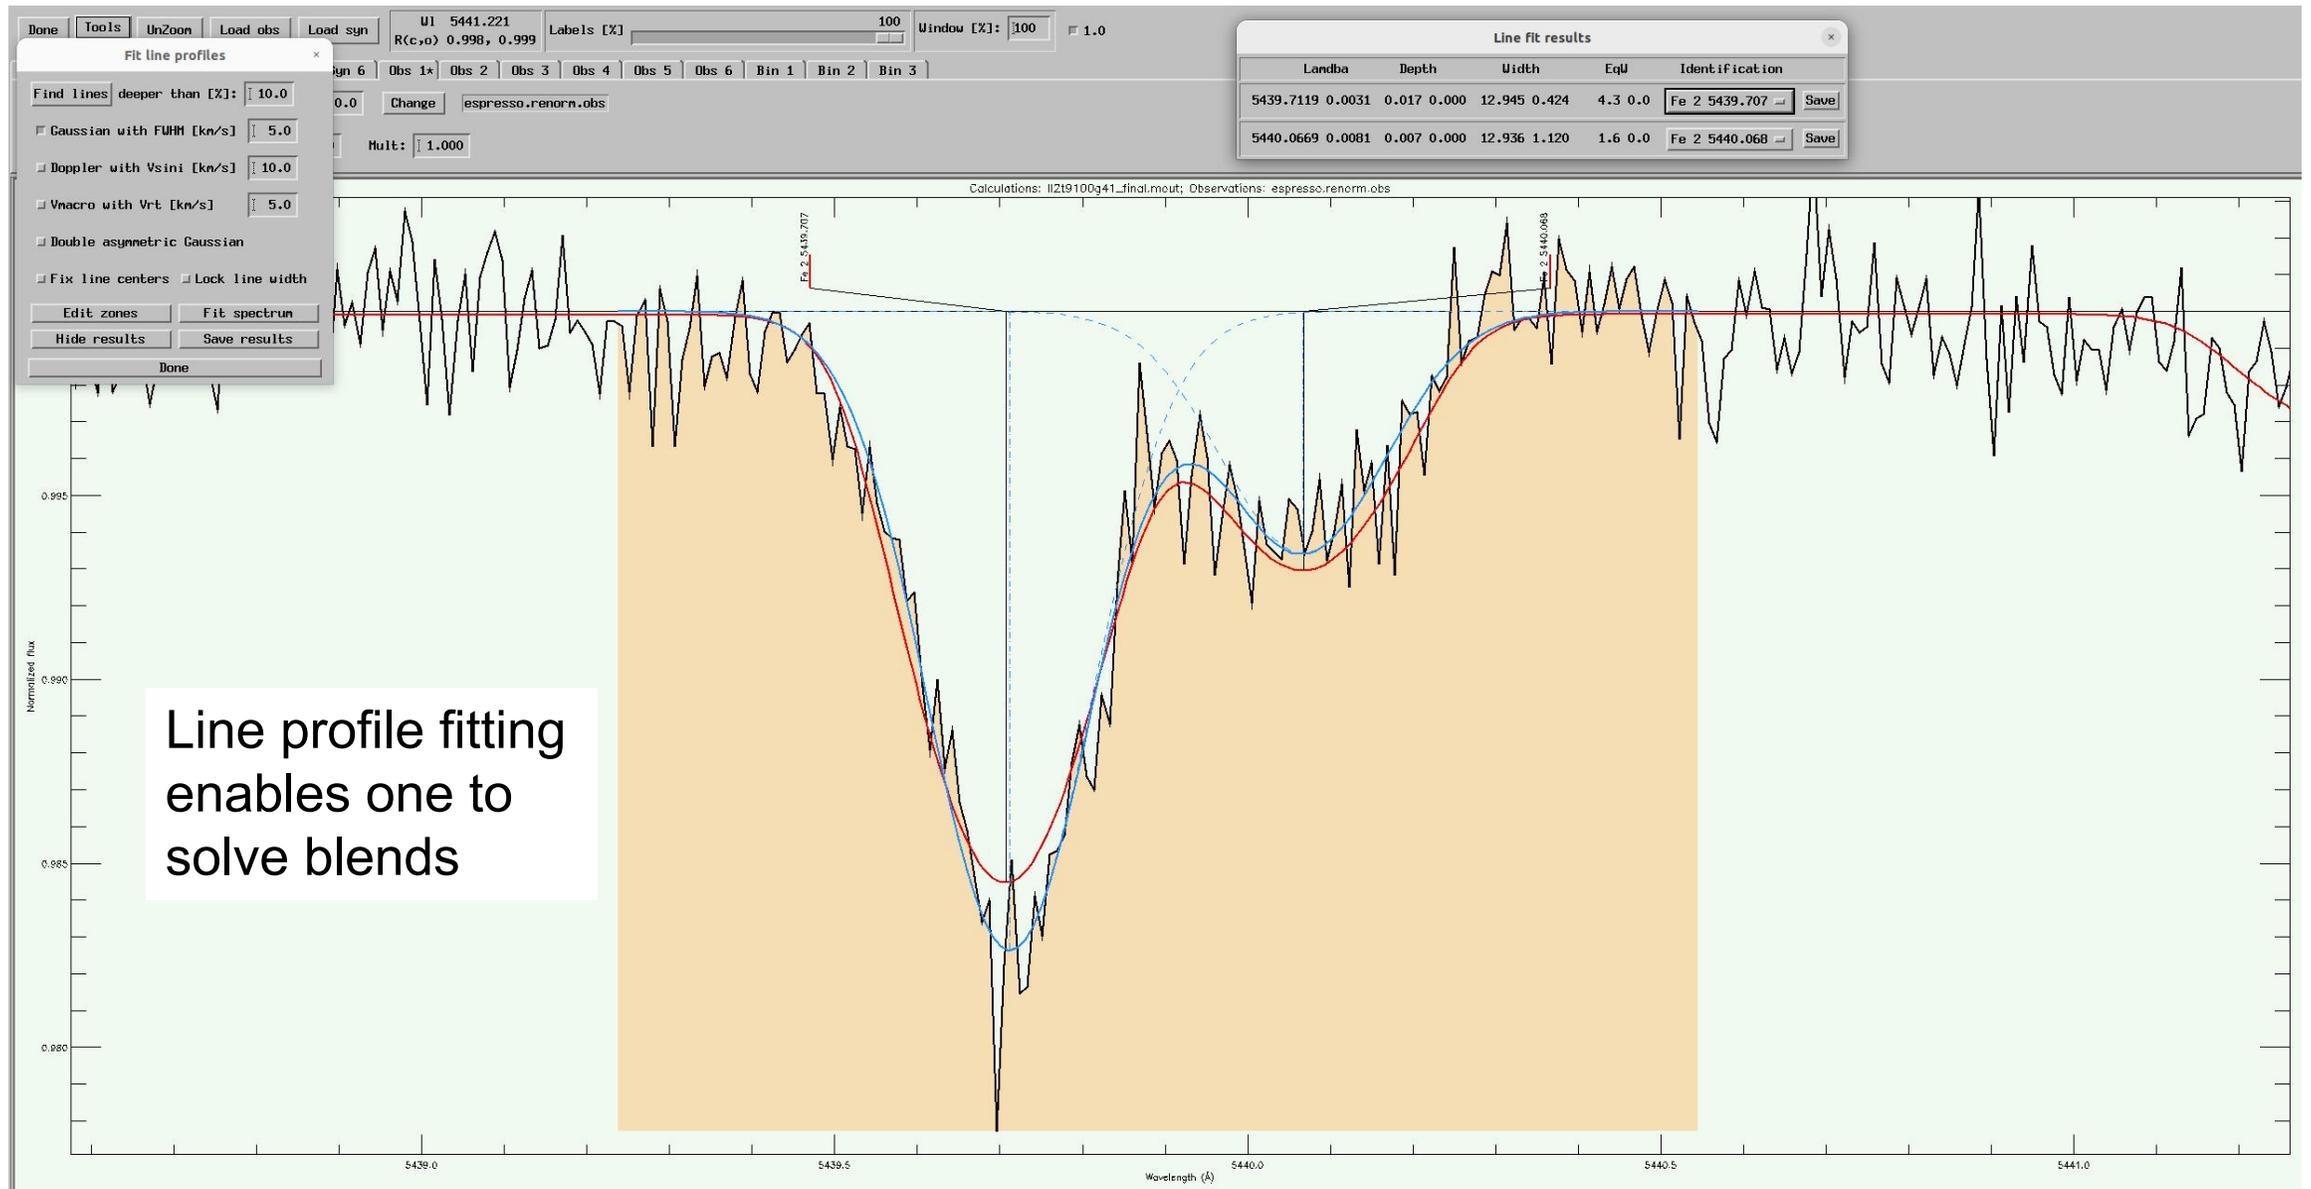

# Equivalent widths: line profile fitting

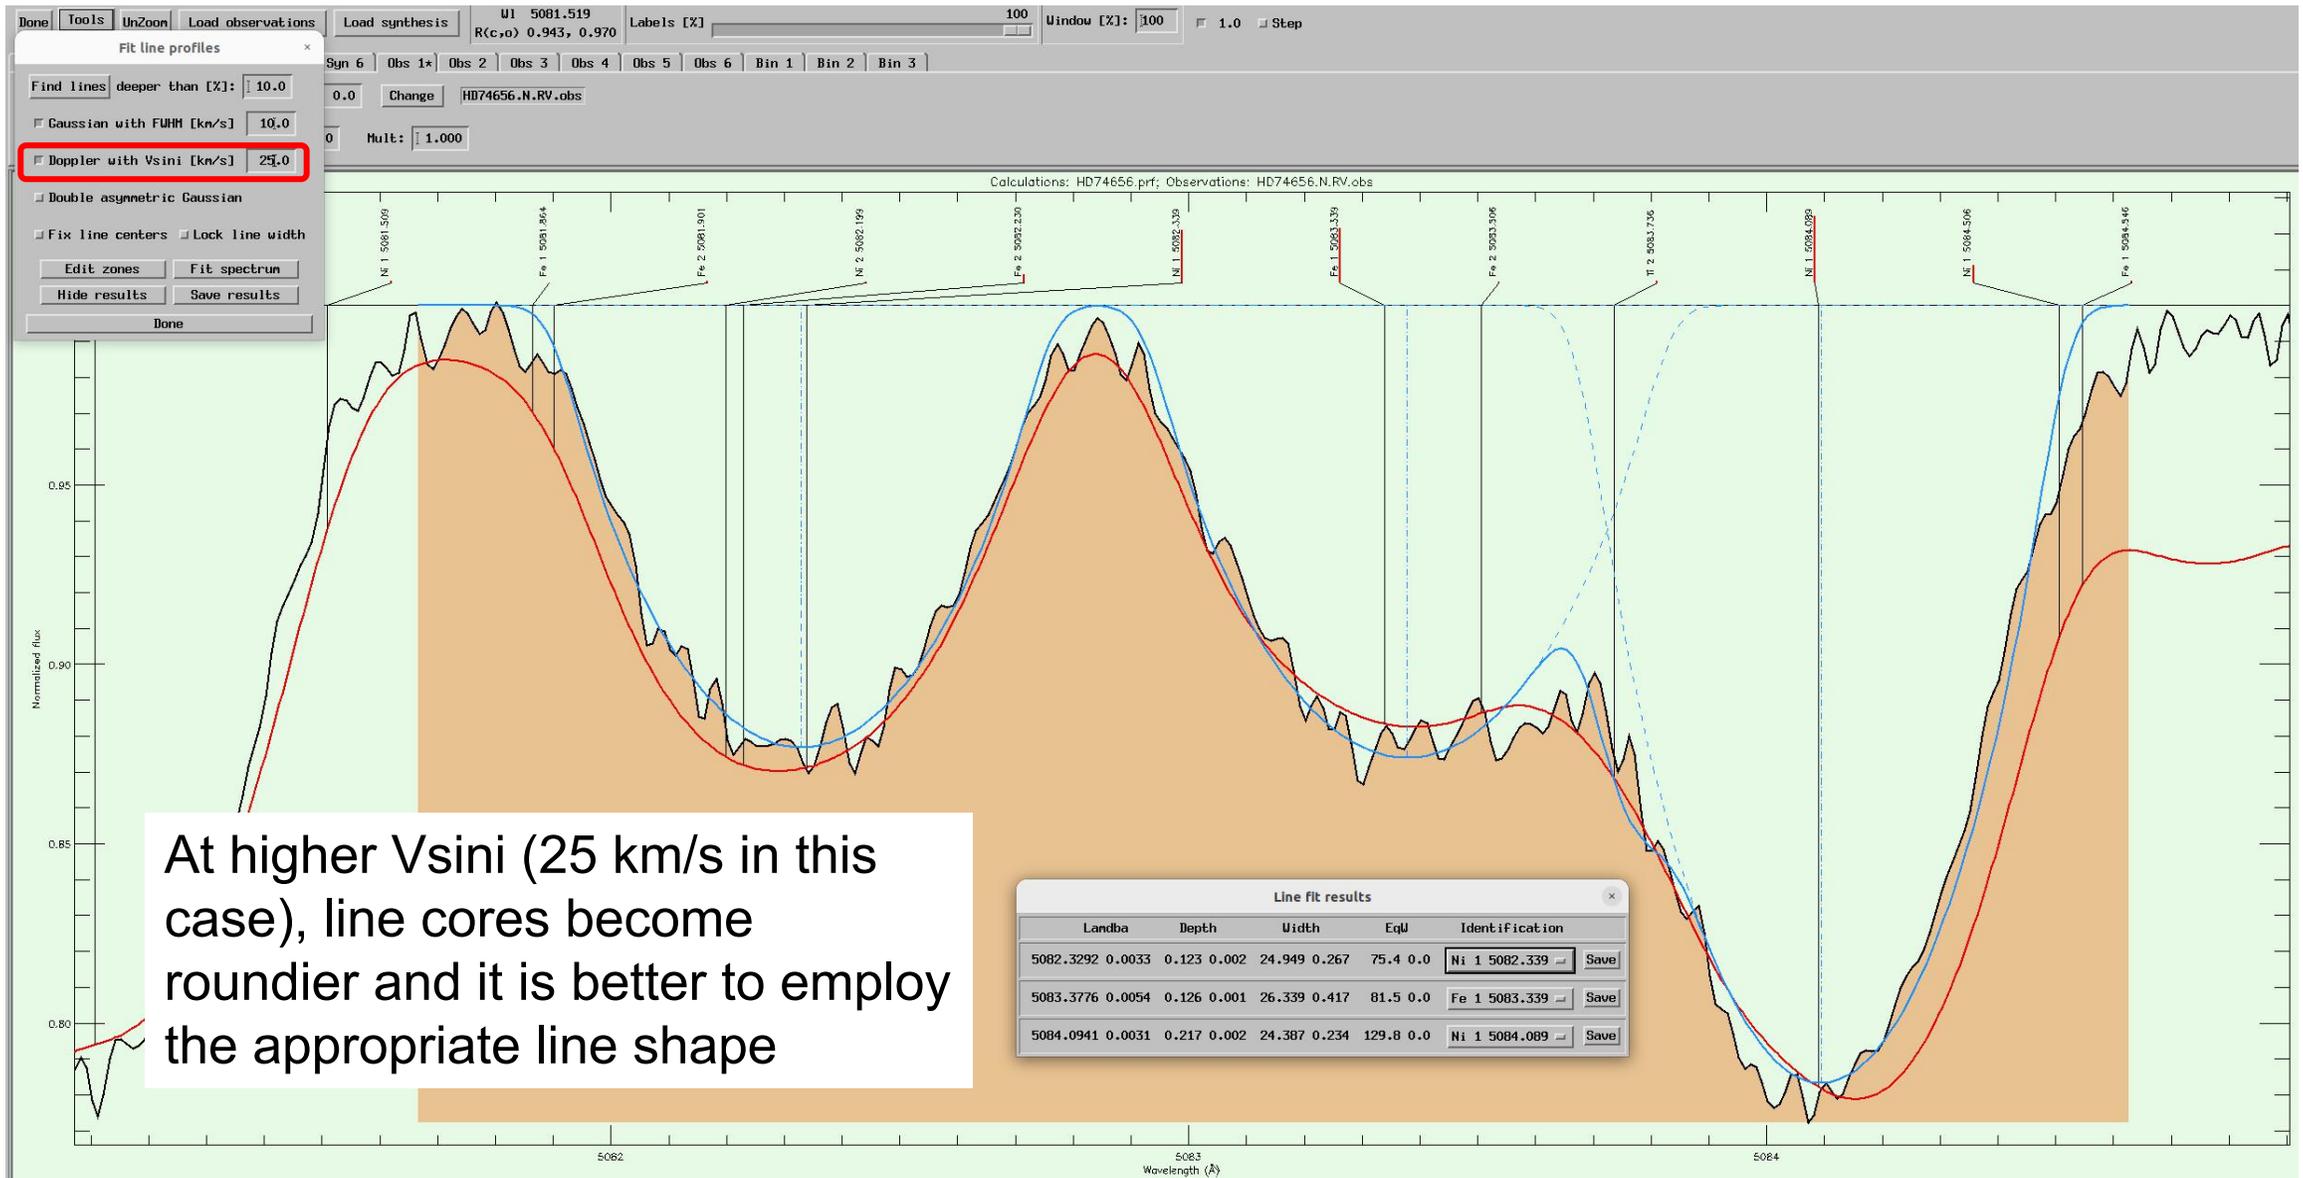

# Equivalent widths: line profile fitting

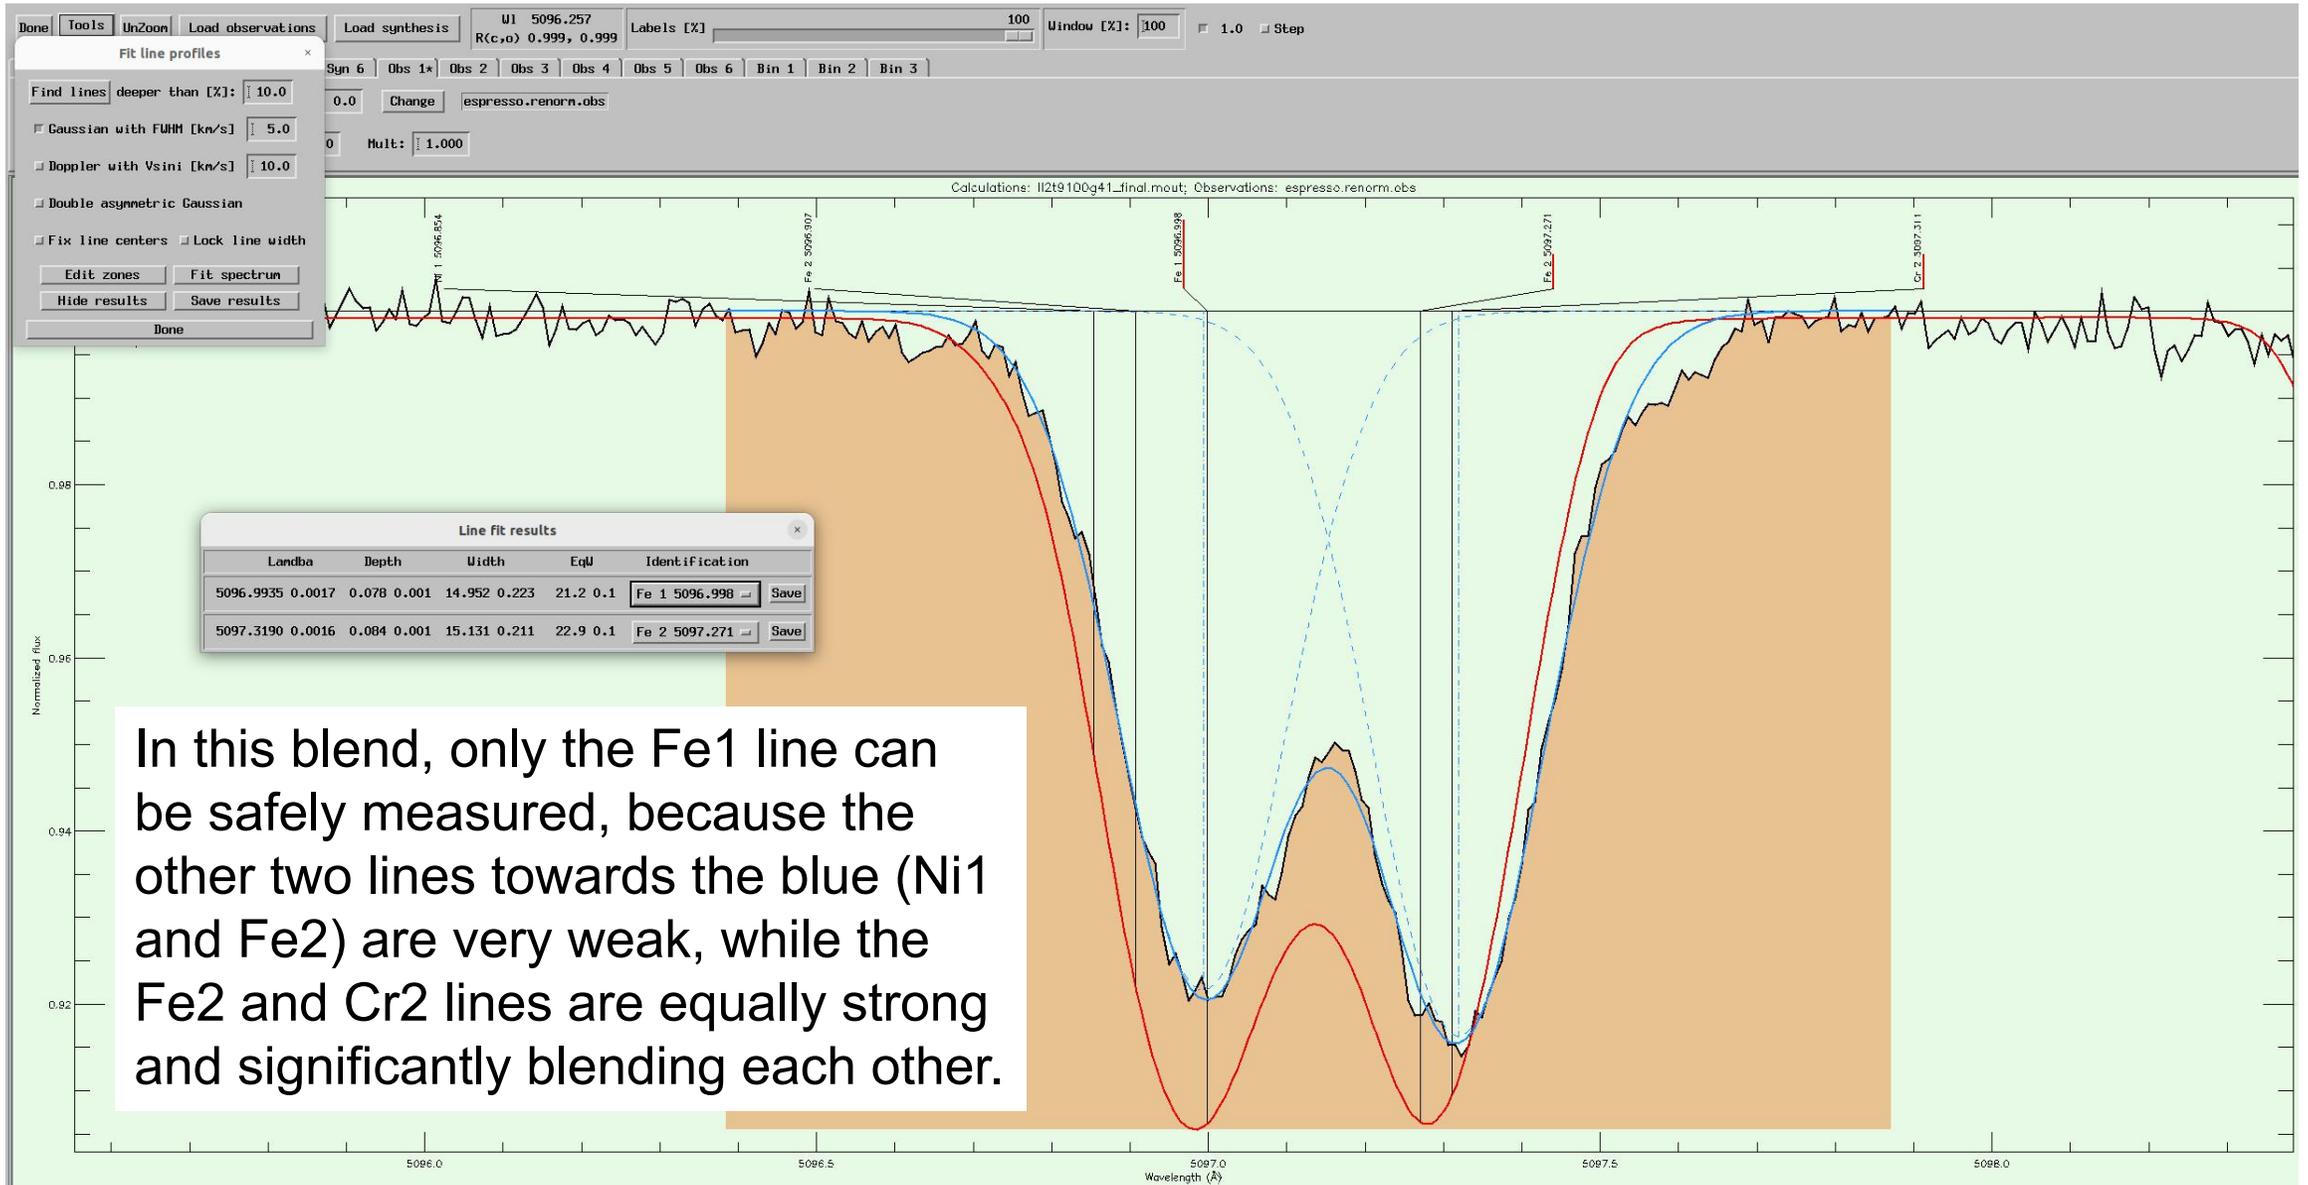

# Equivalent widths: line profile fitting

In this blend, only the Fe1 line can be safely measured, because the other two lines towards the blue (Ni1 and Fe2) are very weak, while the Fe2 and Cr2 lines are equally strong and significantly blending each other.

# Equivalent widths: line profile fitting
